**Abstract:** The electroreduction of small molecules to high value-added chemicals is considered as a promising way to the capture and utilization of atmospheric small molecules, such as O<sub>2</sub>, CO<sub>2</sub> and N<sub>2</sub>. Discovering cheap and efficient electrocatalysts with simultaneously high activity, selectivity, durability and even universality is particularly desirable yet challenging. Herein, we first demonstrate that ultrathin Bi<sub>2</sub>Te<sub>3</sub> nanoplates (NPs), cheap and noble metal-free electrocatalysts, can be adopted as highly universal and robust electrocatalysts, which can efficiently realize the reduction of small molecules (O<sub>2</sub>, CO<sub>2</sub> and N<sub>2</sub>) into targeted products simultaneously. They can achieve high activity and selectivity, as

well as excellent durability of O<sub>2</sub> reduction reaction with almost 100% H<sub>2</sub>O<sub>2</sub> selectivity, CO<sub>2</sub> reduction reaction with up to 90% Faradaic efficiency (FE) of HCOOH as well as N<sub>2</sub> reduction reaction with 7.9% FE of NH<sub>3</sub>. We found that, after electrochemical activation, an obvious Te dissolution happened on the Bi<sub>2</sub>Te<sub>3</sub> NPs, which is the key to the creation of a large amount of Te vacancies in the activated Bi<sub>2</sub>Te<sub>3</sub> NPs. Theoretical calculations revealed that the Te vacancies on the Bi<sub>2</sub>Te<sub>3</sub> surface enable the modulation of the electronic structures of Bi and Te. The Bi and Te are playing the opposite role, in which Bi-6p atoms are the electron suppliers while the Te atoms the electronic depletion center, respectively. Such a highly electroactive surface with a strong preference in supplying electrons for the universal reduction reactions to improve the electrocatalytic performance of Bi<sub>2</sub>Te<sub>3</sub>. Our experiments and theoretical work demonstrated a new class of cheap and versatile catalysts for the electrochemical reduction of small molecules with potential practical applications.

**Keywords:** Bi<sub>2</sub>Te<sub>3</sub> nanoplate • Universality • Oxygen reduction reaction • Carbon dioxide reduction reaction • Nitrogen reduction reaction

In the past years, the utilization and conversion of earth-abundant, atmospheric molecules, such as O<sub>2</sub>, CO<sub>2</sub> and N<sub>2</sub>, have been received many research interests, since it is an efficient way to generate value-added chemical intermediates and fuels. While several typical industrial processes, such as Haber-Bosch process, anthraquinone process etc., are the main routes to produce the important intermediates and fuels (i. e., H<sub>2</sub>O<sub>2</sub>, HCOOH and NH<sub>3</sub>), it still comes with many problems, such as extreme energy dependence, explosion dangers, environmental pollution, limited efficiency and so on.<sup>[1-3]</sup> The electrochemical approach, being milder, cleaner and more efficient, has emerged as a versatile route for yielding the important chemical intermediates and fuels *via* these electrochemical conversions.<sup>[4-8]</sup> In electrocatalysis, while the electrocatalysts play a vital role in reducing the activation energy of

the reaction and driving the reaction, developing highly efficient electrocatalysts is of great significance.

H<sub>2</sub>O<sub>2</sub> is one of the 100 most important chemicals.<sup>[1]</sup> Industrially, H<sub>2</sub>O<sub>2</sub> is prepared by direct oxidation of H<sub>2</sub>, which is however with the danger of explosion.<sup>[9,10]</sup> O<sub>2</sub> reduction reaction (ORR) represents an attractive alternative to prepare H<sub>2</sub>O<sub>2</sub> with the feature of environmentally friendly and safe, but electrocatalysts suffer from high cost, limited selectivity and/or low activity.<sup>[1,2,11,12]</sup> Besides H<sub>2</sub>O<sub>2</sub>, HCOOH, an important intermediate in industry and the chemical fuel in direct HCOOH fuel cells, is a common CO<sub>2</sub> reduction reaction (CO<sub>2</sub>RR) product,<sup>[13-15]</sup> but developing the active, selective, durable and cheap electrocatalysts for CO<sub>2</sub>RR is also very challenging.<sup>[16-21]</sup> NH<sub>3</sub>, another highly value-added chemical, is one of the most widely-used chemicals because it is a source of N<sub>2</sub> for fertilizer and potential transportation fuel.<sup>[22-25]</sup> While N<sub>2</sub> reduction reaction (N<sub>2</sub>RR) into NH<sub>3</sub> represents an attractive prospect for the fixation of N<sub>2</sub>,<sup>[22, 26-30]</sup> it suffers from a low yield rate of NH<sub>3</sub> over reported electrocatalysts.<sup>[31,32]</sup> Based on the above considerations, although small molecules electroreduction is indeed a promising route to obtain value-added chemicals, it is still very challenging to simultaneously reach desirable activity, selectivity and cost. As the electrocatalysts are the key for those reductions, it is particularly urgent to explore low-cost, high-performance catalysts with enhanced efficiency. In particular, it would be a formidable challenge to discover universal electrocatalysts to simultaneously realize high performance for the electroreduction of various small molecules.

Herein, we first demonstrate that the ultrathin Bi<sub>2</sub>Te<sub>3</sub> nanoplates (NPs) can be adopted as highly universal, cheap, active and selective noble metal-free electrocatalysts for small molecules (i. e., O<sub>2</sub>, CO<sub>2</sub> and N<sub>2</sub>) reductions. The ultrathin Bi<sub>2</sub>Te<sub>3</sub> NPs could simultaneously achieve high activity and selectivity, as well as excellent durability for ORR, CO<sub>2</sub>RR as well as N<sub>2</sub>RR. Specifically, the Bi<sub>2</sub>Te<sub>3</sub> NPs showed nearly 100% H<sub>2</sub>O<sub>2</sub> selectivity for ORR, 89.6%

Faradaic efficiency (FE) of HCOOH for CO<sub>2</sub>RR as well as 7.9% FE of NH<sub>3</sub> for N<sub>2</sub>RR. After electrochemical activation, a large amount of Te vacancies were produced on the Bi<sub>2</sub>Te<sub>3</sub> NPs because of the obvious Te dissolution. DFT calculations further verified the formation of Te vacancies will significantly optimize the surface electronic distribution for the electro-reduction towards small molecule reactions. The Bi<sub>2</sub>Te<sub>3</sub> NPs were also stable in the reduction reactions of small molecules with negligible activity decay after the durability tests.

The ultrathin Bi-Te NPs were synthesized through a facile hydrothermal reaction with bismuth chloride (BiCl<sub>3</sub>) and potassium tellurite (K<sub>2</sub>TeO<sub>3</sub>) as precursors, polyvinyl pyrrolidone (PVP, MW = 58000) as surfactant and ethylene glycol as the solvent in the presence of sodium hydroxide (NaOH) (see the supporting information for details). The NPs were initially characterized by high-angle annular dark-field scanning transmission electron microscopy (HAADF-STEM). The hexagonal NPs were the dominant product with a monodisperse edge length of about 450 nm (**Figure 1a**). The thickness of Bi-Te NPs was determined to be around 16.5 nm by atomic force microscope (AFM) (**Figure 1b**). The Bi/Te molar ratio of the NPs was determined to be 2/3 by scanning electron microscopy energy-dispersive X-ray spectroscopy (SEM-EDS) (**Figure S1a**). The powder X-ray diffraction (PXRD) pattern of the products displayed distinct patterns associated with Bi<sub>2</sub>Te<sub>3</sub> materials (**Figure S1b**). In addition, the high-resolution TEM (HRTEM) image of the NP (**Figure 1c**) showed the lattice fringes with an interplanar spacing of 0.222 nm, corresponding to the (110) plane of the Bi<sub>2</sub>Te<sub>3</sub> materials. The Bi<sub>2</sub>Te<sub>3</sub> NPs were further characterized by the line scan analysis, where the distributions of Bi and Te were throughout the whole NP (**Figure 1d**), being consistent with the HAADF-STEM-EDS elemental mapping result (**Figure 1e**).

The prepared Bi<sub>2</sub>Te<sub>3</sub> NPs were then loaded on a commercial carbon (Vulcan XC72R carbon, C) *via* sonication, then thoroughly washed with ethanol for electrocatalysis (**Figure S2**). The commercial Bi<sub>2</sub>Te<sub>3</sub> (**Figure S3**) was taken as reference for comparison. The

commercial  $\text{Bi}_2\text{Te}_3$  were also loaded on a commercial carbon (**Figure S4**). The loading amount of the two catalysts was both 50 wt% based on the inductively coupled plasma atomic emission spectroscopy (ICP-AES). Before the electroreduction, the  $\text{Bi}_2\text{Te}_3$  NPs/C was activated by cycling in 0.1 M KOH for 500 cycles. The double-layer capacitance ( $C_{dl}$ ) values of the  $\text{Bi}_2\text{Te}_3$  NPs/C and the commercial  $\text{Bi}_2\text{Te}_3$ /C were initially tested, which is positively correlated with the electrochemical active surface area (ECSA) (**Figure S5a,c**).<sup>[33,34]</sup> As shown in **Figure S5b,d**, the  $C_{dl}$  of the  $\text{Bi}_2\text{Te}_3$  NPs/C was  $16.7 \text{ mF cm}^{-2}$ , which was much higher than that of the commercial  $\text{Bi}_2\text{Te}_3$ /C ( $3.8 \text{ mF cm}^{-2}$ ). Furthermore, the ECSA of the activated  $\text{Bi}_2\text{Te}_3$  NPs/C was also measured by the  $C_{dl}$  values. As shown in **Figure S6**, the  $C_{dl}$  value of the activated one was  $20 \text{ mF cm}^{-2}$ , which is higher than the initial one ( $16.7 \text{ mF cm}^{-2}$ ). The higher  $C_{dl}$  value of the activated  $\text{Bi}_2\text{Te}_3$  NPs/C is beneficial for enhancing the relevant electroreductions.

The activated  $\text{Bi}_2\text{Te}_3$  NPs/C was initially evaluated as electrocatalyst for ORR. The ORR activity for  $\text{Bi}_2\text{Te}_3$  NPs/C was tested with a rotating ring disk electrode (RRDE) setup at 1600 rpm in  $\text{O}_2$ -saturated 0.1 M KOH. The commercial  $\text{Bi}_2\text{Te}_3$ , carbon and the glassy carbon electrode (GC) were used as the references. The ring electrode was Pt and held at 1.2 V vs. reversible hydrogen electrode (RHE) to oxidize  $\text{H}_2\text{O}_2$  formed on the disk electrode, allowing for ORR product quantification. The collection efficiency (N) is an important parameter to calculate the  $\text{H}_2\text{O}_2$  selectivity. The value of N was experimentally determined to be 0.29 by using a standard ferricyanide system (**Figure S7**).<sup>[35]</sup> **Figure 2a** shows  $\text{O}_2$  reduction disk currents and the simultaneously measured peroxide oxidation ring currents for the activated  $\text{Bi}_2\text{Te}_3$  NPs/C, the commercial  $\text{Bi}_2\text{Te}_3$ /C, carbon and GC. The amount of  $\text{H}_2\text{O}_2$  produced was monitored at the ring electrode, where a positive current was measured once  $\text{H}_2\text{O}_2$  was produced at the disk. The  $\text{H}_2\text{O}_2$  selectivity of the activated  $\text{Bi}_2\text{Te}_3$  NPs/C reached more than 95% at a potential between  $0.2 \text{ V}_{\text{RHE}}$  and  $0.6 \text{ V}_{\text{RHE}}$  (**Figure 2b**), indicating that a high yield of

H<sub>2</sub>O<sub>2</sub> was achievable. As for the commercial Bi<sub>2</sub>Te<sub>3</sub>/C, the H<sub>2</sub>O<sub>2</sub> selectivity was only around 80% at a smaller potential range (0.2 V<sub>RHE</sub> - 0.4 V<sub>RHE</sub>). It should be noted that the H<sub>2</sub>O<sub>2</sub> selectivity of the activated Bi<sub>2</sub>Te<sub>3</sub> NPs/C is the highest in the reported materials, which is even better than many noble-metal catalysts such as Pd-Au,<sup>[11]</sup> Pt-Hg,<sup>[36]</sup> Pd-Hg,<sup>[37]</sup> Au-Pt-Ni<sup>[38]</sup> and so on (**Table S1**). Furthermore, the number of the transferred electrons (*n*) (**Figure 2c**) for the activated Bi<sub>2</sub>Te<sub>3</sub> NPs/C was calculated to be around 2.0 during 0.2 V<sub>RHE</sub> from 0.6 V<sub>RHE</sub>, suggesting a dominant 2-electron O<sub>2</sub> reduction pathway. To further confirm that the ring and disk currents were produced by the reduction of O<sub>2</sub> based on the activated Bi<sub>2</sub>Te<sub>3</sub> NPs/C, we further measured the ORR polarization curve of the activated Bi<sub>2</sub>Te<sub>3</sub> NPs/C by O<sub>2</sub> saturation, where the electrolyte was initially saturated by Ar. The ring and disk current densities of the activated Bi<sub>2</sub>Te<sub>3</sub> NPs/C were close to that in the electrolyte initially saturated by N<sub>2</sub>, indicating that no N<sub>2</sub>RR happens during the ORR process (**Figure S8**). The activated Bi<sub>2</sub>Te<sub>3</sub> NPs/C is also durable since both the ring and disk currents can maintain over 10 h, as revealed by the potentiostatic measurement (**Figure 2d**).

We next investigated the CO<sub>2</sub>RR performance of the activated Bi<sub>2</sub>Te<sub>3</sub> NPs/C in an H-cell containing 30 mL 0.5 M NaHCO<sub>3</sub>. As shown in **Figure 3a**, the activated Bi<sub>2</sub>Te<sub>3</sub> NPs/C showed a remarkable enhancement of the CO<sub>2</sub> reduction. The polarization curve of the activated Bi<sub>2</sub>Te<sub>3</sub> NPs/C in CO<sub>2</sub>-saturated 0.5 M NaHCO<sub>3</sub> showed a cathodic current onset at around -0.7 V<sub>RHE</sub>, and then its current density continued to increase. When the potential reached to -1.1 V<sub>RHE</sub>, the activated Bi<sub>2</sub>Te<sub>3</sub> NPs/C could reach a current density of about 31 mA cm<sup>-2</sup>, significantly higher than that of the commercial Bi<sub>2</sub>Te<sub>3</sub>/C. The reduction reactions of Te<sup>2+</sup> and Bi<sup>3+</sup> caused the reduction peaks at -0.5 V<sub>RHE</sub> and 0.35 V<sub>RHE</sub>, respectively.<sup>[39,40]</sup> In the control experiment, the polarization curves in the Ar-saturated 0.5 M NaHCO<sub>3</sub> of the activated Bi<sub>2</sub>Te<sub>3</sub> NPs/C and the commercial Bi<sub>2</sub>Te<sub>3</sub>/C showed that the current densities were significantly reduced. To identify and quantify the reduction products, gas chromatography

and  $^1\text{H}$  NMR spectroscopy were performed to quantify the gaseous and liquid products, respectively. The product in  $\text{CO}_2\text{RR}$  included  $\text{HCOOH}$ ,  $\text{CO}$ , and  $\text{H}_2$  over the activated  $\text{Bi}_2\text{Te}_3$  NPs/C and the commercial  $\text{Bi}_2\text{Te}_3/\text{C}$ . We found that  $\text{HCOOH}$  was the major product, along with a small amount of  $\text{CO}$  and  $\text{H}_2$ . FEs of  $\text{HCOOH}$ ,  $\text{CO}$  and  $\text{H}_2$  at various potentials were calculated and summarized in **Figure 3b** and **Figure S9**. We can see that the activated  $\text{Bi}_2\text{Te}_3$  NPs/C showed more than 70%  $\text{FE}_{\text{HCOOH}}$  over a wide voltage range. When the potential was increased to  $-0.9 \text{ V}_{\text{RHE}}$ , the  $\text{FE}_{\text{HCOOH}}$  reached up to 89.6% (**Figure S10**). In addition, the  $\text{FE}_{\text{CO}}$  was less than 3% at the wide range of applied potentials. The  $\text{FE}_{\text{H}_2}$  underwent a significant decrease with increasing potential, where only small  $\text{FE}_{\text{H}_2}$  was detected at the high potentials. For the commercial  $\text{Bi}_2\text{Te}_3/\text{C}$ , the  $\text{FE}_{\text{HCOOH}}$  reached the peak value of only 58.1% at  $-0.8 \text{ V}_{\text{RHE}}$  (**Figure 3b**). Therefore, the  $\text{FE}_{\text{HCOOH}}$  for the activated  $\text{Bi}_2\text{Te}_3$  NPs/C was higher than the most state of the art catalysts for  $\text{HCOOH}$  productions in  $\text{CO}_2\text{RR}$  (**Table S2**). The  $\text{FE}_{\text{HCOOH}}$  for the activated  $\text{Bi}_2\text{Te}_3$  NPs/C was even comparable to the value for the partially oxidized Co layers reported in Nature.<sup>[41]</sup> Furthermore, the partial current densities of  $\text{HCOOH}$  for the different catalysts were further calculated and plotted against the working potential (**Figure 3c**). The activated  $\text{Bi}_2\text{Te}_3$  NPs/C delivered a maximum value of  $j_{\text{HCOOH}} = 24.2 \text{ mA cm}^{-2}$  at  $-1.1 \text{ V}_{\text{RHE}}$ , whereas that of the latter was only  $5.2 \text{ mA cm}^{-2}$ . The activated  $\text{Bi}_2\text{Te}_3$  NPs/C also showed enhanced durability with maintaining high  $\text{FE}_{\text{HCOOH}}$  of 88.7% after 10 h potentiostatic test at  $-0.9 \text{ V}_{\text{RHE}}$  (**Figure S11**).

Inspired by the excellent performance of the activated  $\text{Bi}_2\text{Te}_3$  NPs/C for ORR and  $\text{CO}_2\text{RR}$ , the performance of the activated  $\text{Bi}_2\text{Te}_3$  NPs/C for  $\text{N}_2\text{RR}$  was further investigated. The polarization curves of the activated  $\text{Bi}_2\text{Te}_3$  NPs/C and the commercial  $\text{Bi}_2\text{Te}_3/\text{C}$  in both Ar-saturated and  $\text{N}_2$ -saturated 0.1 M KOH were first tested (**Figure 3d**). For the activated  $\text{Bi}_2\text{Te}_3$  NPs/C, the current density in  $\text{N}_2$ -saturated electrolyte was higher than that in the Ar-saturated one from  $-0.3 \text{ V}_{\text{RHE}}$  to  $-0.8 \text{ V}_{\text{RHE}}$ , indicating that activated  $\text{Bi}_2\text{Te}_3$  NPs/C had

potential response toward N<sub>2</sub>RR. By contrast, the commercial Bi<sub>2</sub>Te<sub>3</sub>/C exhibited similar polarization curve in both Ar-saturated and N<sub>2</sub>-saturated electrolytes, suggesting its low activity toward N<sub>2</sub>RR. The potentiostatic tests were further conducted in N<sub>2</sub>-saturated 0.1 M KOH solution at different potentials for 2 h (**Figure S12**). The FEs of NH<sub>3</sub> were calculated by the detection of different potential liquid products based on UV spectrophotometer. As shown in **Figure 3e**, the FE<sub>NH<sub>3</sub></sub> for the activated Bi<sub>2</sub>Te<sub>3</sub> NPs/C was higher than that of the commercial Bi<sub>2</sub>Te<sub>3</sub>/C at all applied potentials. Remarkably, the FE<sub>NH<sub>3</sub></sub> for activated Bi<sub>2</sub>Te<sub>3</sub> NPs/C reached 7.9% at -0.4 V<sub>RHE</sub>, which was 1.82-fold higher than that of the commercial Bi<sub>2</sub>Te<sub>3</sub>/C (4.3%). The FE<sub>NH<sub>3</sub></sub> for the activated Bi<sub>2</sub>Te<sub>3</sub> NPs/C was higher than many non-noble metals-based catalysts and even outperformed several typical noble-metal catalysts, such as Au nanorods<sup>[22]</sup> (**Table S3**). Moreover, the yield rates for NH<sub>3</sub> of the different catalysts were further investigated. As shown in **Figure 3f**, the rate increased as the negative potential increased until -0.4 V<sub>RHE</sub>, where an average value of NH<sub>3</sub> is 3.9 μg<sub>NH<sub>3</sub></sub> h<sup>-1</sup> cm<sup>-2</sup>. As the potential reached below -0.4 V<sub>RHE</sub>, the hydrogen evolution reaction becomes the major reaction, as revealed by the polarization curve shown in **Figure 3d**. In control experiments (**Figure S13**), when N<sub>2</sub> was replaced by Ar, while keeping other reaction parameters unchanged, NH<sub>3</sub> could not be identified in the electrolyte. The same was observed when the activated Bi<sub>2</sub>Te<sub>3</sub> NPs/C was replaced by a carbon paper or carbon. These control experiments confirmed that NH<sub>3</sub> was produced from the N<sub>2</sub>RR catalyzed by the activated Bi<sub>2</sub>Te<sub>3</sub> NPs/C. To corroborate the origin of the NH<sub>3</sub> generated from N<sub>2</sub>RR, we designed isotopic labelling study using <sup>15</sup>N<sub>2</sub> as the feeding gases.<sup>[42,43]</sup> The obtained <sup>15</sup>NH<sub>4</sub><sup>+</sup> and <sup>14</sup>NH<sub>4</sub><sup>+</sup> were measured by <sup>1</sup>H NMR spectroscopy of the reaction solution. The <sup>1</sup>H NMR spectra of the standards and the yielded <sup>14</sup>NH<sub>4</sub><sup>+</sup> and <sup>15</sup>NH<sub>4</sub><sup>+</sup> were shown in **Figure S14**. The isotopic labelled sample exhibited doublets, which correspond to <sup>15</sup>NH<sub>4</sub><sup>+</sup>. When using pure <sup>14</sup>N<sub>2</sub> as a reference, triplets corresponding to <sup>14</sup>NH<sub>4</sub><sup>+</sup> can be found. Those results confirm that the yielded NH<sub>3</sub> resulted from the activated Bi<sub>2</sub>Te<sub>3</sub> NPs/C catalyzed N<sub>2</sub>RR. Finally, the durability of the activated

Bi<sub>2</sub>Te<sub>3</sub> NPs/C was tested by scanning at a constant potential of -0.4 V<sub>RHE</sub> for 10 h (**Figure S15**), where the activated Bi<sub>2</sub>Te<sub>3</sub> NPs/C maintained almost the same FE<sub>NH<sub>3</sub></sub> as the initial value.

To understand the intrinsic reason for the high performance of the Bi<sub>2</sub>Te<sub>3</sub> NPs/C towards small molecules electroreduction, the Bi<sub>2</sub>Te<sub>3</sub> NPs/C at the different stages during the catalytic process were characterized in detail. Before the electroreduction, the Bi<sub>2</sub>Te<sub>3</sub> NPs/C was activated by cycling in 0.1 M KOH for 500 cycles. We can see that the activated Bi<sub>2</sub>Te<sub>3</sub> NPs/C are porous structure (**Figure 4a**) with partial dissolution of Te (**Figure 4b**). The atomic ratio of Bi/Te changed from 40.6/59.4 into 62.3/37.7, as revealed by SEM-EDS, which was in lined with the ICP-AES results (**Table S4**). In addition, the EDS mappings showed that Bi and Te still distributed on the NPs uniformly (**Figure 4c**). HRTEM image revealed that the lattices were discontinuous in the activated Bi<sub>2</sub>Te<sub>3</sub> NPs/C (**Figure 4d**). Therefore, the atomic arrangement of the activated Bi<sub>2</sub>Te<sub>3</sub> NPs/C showed obvious structure change at the surface, which would affect the catalytic performance.<sup>[44,45]</sup> In addition, the discontinuous lattice formed by the obvious Te dissolution could lead to the formation of Te vacancies. The Bi 4f and Te 3d spectra of the activated Bi<sub>2</sub>Te<sub>3</sub> NPs/C showed that both the surface Bi and surface Te were in the oxidation state, as revealed by X-ray photoelectron spectroscopy (**Figure S16**).

The activated Bi<sub>2</sub>Te<sub>3</sub> NPs/C after ORR durability test was also investigated in detail. As shown in **Figure S17a**, they could still be well-dispersed on the carbon support, and the atomic ratio of Bi/Te could be largely maintained (69.5/30.5) (**Figure 4b**). Discontinuous lattices could also be observed here (**Figure S17b**). Furthermore, both Bi and Te still distributed on the NPs uniformly (**Figure S17c**). Based on the above experimental results, we further summarized the schematic diagram of the morphology and structural evolution of the Bi<sub>2</sub>Te<sub>3</sub> NPs/C during ORR in **Figure 4e**. After electrochemical activation, the NPs changed to be a porous structure due to the partial dissolution of Te. As the reaction proceeds, the NPs maintained a porous hexagonal NP structure after the durability test, except that the degree of

porosity increases slightly with the further minor dissolution of Te. Above all, after the ORR durability test, the activated  $\text{Bi}_2\text{Te}_3$  NPs/C could largely maintain their structure and composition, showing excellent ORR durability. As for  $\text{CO}_2\text{RR}$  and  $\text{N}_2\text{RR}$ , the activated  $\text{Bi}_2\text{Te}_3$  NPs/C also exhibited good durability (**Figure S18-19**) with negligible changes in selectivity, composition, morphology and structure. In addition, the performances of the  $\text{Bi}_2\text{Te}_3$  and commercial  $\text{Bi}_2\text{Te}_3$  for ORR,  $\text{CO}_2\text{RR}$  and  $\text{N}_2\text{RR}$  have been included (**Figure S20-22**). As we can see, if the materials were not loaded on the carbon, their performances for the electrochemical reduction reactions are much worse.

Especially, Te vacancies formed after the Te dissolution from the  $\text{Bi}_2\text{Te}_3$  NPs/C during the activation process may play a key role in the reduction reaction. To further confirm that the Te vacancies promote the activities of small molecules reduction in experiment, we compared the performances for ORR,  $\text{CO}_2\text{RR}$  and  $\text{N}_2\text{RR}$  of the  $\text{Bi}_2\text{Te}_3$  NPs/C before and after electrochemical activation. We can see that the  $\text{Bi}_2\text{Te}_3$  NPs/C without electrochemical activation exhibits much worse performances (**Figure S23-24**), clearly showing the important role of Te vacancies in the small molecules reduction reaction.

The DFT calculations have been carried out for the insightful understanding of such reduction active materials. To clearly observe the evident effect brought by the surface defect, the electronic distribution of bonding and anti-bonding near the Fermi level ( $E_F$ ) between the pristine  $\text{Bi}_2\text{Te}_3$  and defective  $\text{Bi}_2\text{Te}_3$  with vacancy Te ( $V_{\text{Te}}$ ) is presented. For the pristine  $\text{Bi}_2\text{Te}_3$ , the electronic distribution shows the coupling between the HOMO and LUMO. However, when the surface Te vacancy is introduced to the lattice, the charge density distribution of bonding and antibonding orbitals has obviously turned from delocalized to localized (**Figure 5a-5b**). The formation of the surface defect will significantly reconstruct the surface electronic distribution to activate the electroactivity for molecule reduction. To gain more insight into the origin of the electroactivity, we further interpret the electronic

properties given by different regions of  $\text{Bi}_2\text{Te}_3$ . With the introduction of surface Te vacancy, the Bi-6p has been significantly activated when compared to the pristine  $\text{Bi}_2\text{Te}_3$ . The Bi-6p bands has been boosted up with 0.87 eV towards the Fermi level, confirming the overall enhanced electroactivity (**Figure 5c**). From the deep layer to the surface of  $\text{Bi}_2\text{Te}_3$ , the evolution of the projected partial density of states (PDOS) of Te displays a gradual migration to the higher position close to  $E_F$  (**Figure 5d**). The surface Te has been activated from  $E_F - 1.25$  eV to  $E_F - 0.25$  eV with a positive 1.00 eV band offset, which is consistent with the electronic distribution change with  $V_{\text{Te}}$ . Simultaneously, the similar activation of Bi is also noted, in which the dominant Bi-6p bands have been boosted from  $E_F - 1.75$  eV to  $E_F - 3.25$  eV with a positive 1.25 eV band offset (**Figure 5e**). The Bi-bands locates at a lower position than Te-bands supports an electron-rich character. The migration of p-bands of surface metal to the  $E_F$  imply an oxidation state that is in a good agreement with the XPS results. Thus, the surface defect  $V_{\text{Te}}$  has largely promoted the reduction ability of  $\text{Bi}_2\text{Te}_3$  based on the excitation of surface electron-rich Bi and electron-depletion channel Te to reach the optimal electronic environment for reduction reactions.

The optimal adsorption of key reactants, products and intermediates of ORR,  $\text{CO}_2\text{RR}$  and  $\text{N}_2\text{RR}$  are shown in **Figure 5f-h**. The summary of the adsorption energies and bond length is supplied in **Table S5**. The active bonding between the surface and adsorbates with only slight distortion on the local  $\text{Bi}_2\text{Te}_3$  structure demonstrates a smooth and stable reduction process depends on the electroactive surface, which confirms the good durability tests. We further analyze the universal reduction reactivity of  $\text{Bi}_2\text{Te}_3$  from an energetic perspective regarding the free energy of the reaction pathway of ORR,  $\text{N}_2\text{RR}$  in alkaline condition and  $\text{CO}_2\text{RR}$  in acidic condition. To achieve high selectivity of  $\text{H}_2\text{O}_2$  with 2-electron transfer rather than the conventional 4-electron ORR, the determining step by the formation of the key intermediate  $[\text{OOH}]^*$  become pivotal (**Figure 5i**). Notably,  $[\text{OOH}]^*$  shows much stronger

downhill towards the formation of  $[\text{H}_2\text{O}_2]^*$  rather than the dissociation of O-H bonding. The further adsorption of the proton from water dissociation to form  $[\text{H}_2\text{O}_2]^*$  exhibits a significant drop that is nearly 2 eV larger than the formation of  $[\text{O}]^*$ , which is in a good agreement with the ultra-high selectivity of  $\text{H}_2\text{O}_2$  during the operation range. Furthermore, the spontaneous desorption of  $\text{H}_2\text{O}_2$  will ensure efficient 2-electron ORR. Further investigation of  $\text{CO}_2\text{RR}$  also reflects an energetically preferred reaction with total reaction releases heat of 0.35 eV. (**Figure 5j**). The first adsorption of the proton is prone to the formation of  $[\text{HCOO}]^*$  rather than  $[\text{COOH}]^*$ . The formation of  $[\text{COOH}]^*$  will confront an energy barrier of 0.27 eV that leads to a lower  $\text{CO}_2\text{RR}$  efficiency when compared with the route of  $[\text{HCOO}]^*$ . The transition barrier of the  $\text{CO}_2\text{RR}$  is 0.17 and 0.31 eV, respectively. The continuous downhill physiochemical trend of  $\text{CO}_2\text{RR}$  supports a good reactivity while the appropriate adsorption energy of  $\text{HCOOH}$  will also ensure a good efficiency. For the  $\text{N}_2\text{RR}$  process, the first protonation process of the  $\text{N}_2$  molecule is usually considered as the determining step for the  $\text{N}_2\text{RR}$ .<sup>[46]</sup> For the surface defective  $\text{Bi}_2\text{Te}_3$ , the key energy barrier is 0.36 V at zero electrode potential ( $U = 0$  V) (**Figure 5k**). When  $U = -0.36$  V is applied, the whole  $\text{N}_2\text{RR}$  becomes spontaneous, which is closer to the polarization curve test. As an important indicator to evaluate the  $\text{N}_2\text{RR}$  performance, we calculate the overpotential  $\eta$  according to  $U(\text{equilibrium}) - U(\text{rate-limiting})$ , where the  $U(\text{equilibrium})$  is around about -0.16 V for the reaction  $\text{N}_2\text{RR}$ . Thus, the overpotential of  $\text{N}_2\text{RR}$  on  $\text{Bi}_2\text{Te}_3$  will be  $(-0.16) - (-0.36) = 0.2$  V, which is lower than some previously well-studied systems such as Ru and Re,<sup>[47]</sup> indicating the great electroactivity towards  $\text{N}_2\text{RR}$  of the surface defective  $\text{Bi}_2\text{Te}_3$ . Therefore, both the electronic and energetic analysis demonstrates the great electroactivity towards the reduction reactions. The defect-induced optimized surface electronic environment endows  $\text{Bi}_2\text{Te}_3$  great potential as a promising multi-functional electrocatalyst for facile synthesis of highly valuable small molecules for broad applications in industrials.

In conclusion, we first demonstrated that ultrathin Bi<sub>2</sub>Te<sub>3</sub> NPs can be adopted as highly universal and robust electrocatalysts for the reduction of small molecules (O<sub>2</sub>, CO<sub>2</sub> and N<sub>2</sub>). When the activated Bi<sub>2</sub>Te<sub>3</sub> NPs/C was evaluated as the ORR electrocatalyst in 0.1 M KOH, it exhibited excellent ORR selectivity toward H<sub>2</sub>O<sub>2</sub> production with almost 100% selectivity between 0.2 V<sub>RHE</sub> and 0.6 V<sub>RHE</sub>. When the activated Bi<sub>2</sub>Te<sub>3</sub> NPs/C was adopted as CO<sub>2</sub>RR electrocatalyst in 0.5 M NaHCO<sub>3</sub>, it enabled superior activity with large HCOOH partial current density of 24.2 mA cm<sup>-2</sup> at -1.1 V<sub>RHE</sub>, as well as excellent selectivity with FE<sub>HCOOH</sub> of 89.6%. As for the N<sub>2</sub>RR, the activated Bi<sub>2</sub>Te<sub>3</sub> NPs/C had been demonstrated to serve as a highly efficient electrocatalyst for N<sub>2</sub>RR with the FE<sub>NH<sub>3</sub></sub> of 7.9% for at -0.4 V<sub>RHE</sub> in 0.1 M KOH. They also showed enhanced durability after a long period of electrolysis for all the three electrocatalytic reactions. Detailed characterizations revealed that, after electrochemical activation, an obvious Te dissolution happened on the Bi<sub>2</sub>Te<sub>3</sub> NPs, which creates a large amount of Te vacancies in the activated Bi<sub>2</sub>Te<sub>3</sub> NPs. Theoretical calculations confirmed that the formation of Te vacancy will completely modulate the surface of Bi<sub>2</sub>Te<sub>3</sub> towards electroactive and reductive feature as the active sites for the universal for the high-valued small molecules via energetically favorable pathways. This work not only showed that the activated Bi<sub>2</sub>Te<sub>3</sub> NPs/C are universal catalysts for the electroreduction of small molecules, but also provided a powerful material foundation for potential electrocatalysis.

## The table of contents entry

The ultrathin activated  $\text{Bi}_2\text{Te}_3$  nanoplates (NPs) have been demonstrated as highly universal and robust electrocatalysts for the electroreduction of small molecules ( $\text{O}_2$ ,  $\text{CO}_2$  and  $\text{N}_2$ ), where they exhibit nearly 100%  $\text{H}_2\text{O}_2$  selectivity for ORR, 89.6% Faradaic efficiency (FE) of  $\text{HCOOH}$  for  $\text{CO}_2\text{RR}$  and 7.9% FE of  $\text{NH}_3$  for  $\text{N}_2\text{RR}$ , as well as enhanced durability, showing a new class of robust electrocatalysts for small molecules conversion with potential practical applications.

**Keyword:**  $\text{Bi}_2\text{Te}_3$  nanoplate • Universality • Oxygen reduction reaction • Carbon dioxide reduction reaction • Nitrogen reduction reaction

## Exploring $\text{Bi}_2\text{Te}_3$ nanoplates as versatile catalysts for electrochemical reduction of small molecules
