## Abstract

**Purpose:** To evaluate the influence of 2.2 mm clear corneal incision (CCI) features in surgically induced astigmatism (SIA) and higher-order aberrations (HOAs) after cataract surgery.

**Methods:** Right eyes of 92 subjects receiving 2.2 mm incision cataract surgery were involved. 38 eyes were categorized as the intact incision group and 54 eyes were the defective incision group. Pre- and post-operative (1 month and 6 months) corneal astigmatism and HOAs on anterior and posterior corneal surfaces, corneal volume and corneal thickness (CT) were measured using Pentacam. The CCI features including incision length (IL), incision angles, distance from incision to central cornea (Dis-En/Ex), CT at incision site, were quantified using AS-OCT.

**Results:** The defective incision group showed shorter IL and larger incision angles [false discovery rate (FDR)- $P < .05$ ]. Changes in CT at incision site were more pronounced for the defective incision group (FDR- $P < .05$ ). Some SIA parameters were related to the certain specific CCI features, especially IL (FDR- $P < .05$ ). Both groups exhibited significant increased 6 mm posterior corneal tHOAs at 1 month (Bonferroni corrected- $P < .01$ ) and the defective incision group showed increased 6 mm posterior tHOAs at 6 months (Bonferroni corrected- $P = .023$ ). There were characteristic correlations between Zernike terms and CCI features including IL, CT, Dis-En/Ex, incision angles at 1 month, especially over 6 mm zone.

1  
2  
3  
4 **Conclusion:** The CCI deformities can affect corneal recovery and induce more  
5  
6 HOAs at 1 month postoperatively. Such effects became minor, but could persist  
7  
8 until 6 months. The IL combined with Angle-En/Ex was important factor  
9  
10 influencing CCI integrity and corneal optical quality.

## Introduction

Surgically induced astigmatism (SIA) after cataract surgery and its impact on corneal optical quality have been well-documented (Kim et al. 2016; Hayashi et al. 2018). However, apart from astigmatism, the higher-order aberrations (HOAs) are also important for visual quality (Namba et al. 2017; Hughes et al. 2020). Previous studies (von Sonnleithner et al. 2017; He et al. 2019) have observed significantly increased corneal HOAs after cataract surgery and its association with less than optimal visual quality (Namba et al. 2017). The surgical procedures, including clear corneal incision (CCI), phacoemulsification, stromal hydration and intraoperative flushing, may all affect corneal regularity on both the anterior and posterior corneal surfaces and consequently induce the HOAs.

Studies have demonstrated that a wider CCI causes more SIA and corneal HOAs changes (Denoyer et al. 2013; He et al. 2019), particularly at the posterior corneal surface (Ye et al. 2014; Hidaka et al. 2016; He et al. 2019). Apart from the incision width, the other fine architecture features of CCI, such as incision length (IL), deformities, distance to central cornea, may also be important for the degradation of postoperative corneal optical quality and deserving of further investigation. Since incomplete sealing frequently occurs at the internal wound site of CCI (Vasavada et al. 2013), one can speculate that the resulting corneal deformities could affect the corneal optical quality after cataract surgery.

1  
2  
3  
4 With widespread adoption of sophisticated technologies like femtosecond  
5  
6 laser, multifocal and toric IOLs, the quality of CCI have become a more  
7  
8 prominent determinant for the visual quality outcome of the cataract surgery.  
9  
10  
11 However, to the best of our knowledge, there is no published study looking at  
12  
13 the relationship between the CCI features and HOAs, especially on the  
14  
15 posterior corneal surface.  
16  
17  
18

19  
20 The fine CCI features can be evaluated with the anterior segment optical  
21  
22 coherence tomography (AS-OCT) (Nguyen & Chopra 2013; Lim 2015).  
23  
24 Previous studies (Dupont-Monod et al. 2009; Xia et al. 2009; Can et al. 2011)  
25  
26 evaluated corneal stromal edema around the CCI area on AS-OCT images.  
27  
28 The CCI architecture deformities, including endothelial gap and Descemet  
29  
30 membrane detachment (DMD), were also described using AS-OCT  
31  
32 measurement (Calladine & Packard 2007; Xia et al. 2009; Chee et al. 2010;  
33  
34 Can et al. 2011).  
35  
36  
37  
38  
39

40 Therefore, the present work quantified the CCI architecture parameters,  
41  
42 including IL, entry/exit angle, distance from incision to central cornea, corneal  
43  
44 thickness (CT) at incision site, using AS-OCT in a group of patients receiving  
45  
46 2.2 mm incision phacoemulsification cataract surgery. The aim was to evaluate  
47  
48 the role of the CCI architecture parameters in the postsurgical corneal SIA and  
49  
50 HOAs at 1 month and 6 months after surgery. This work could contribute to the  
51  
52 optimization of the CCI design and increase the accuracy or predictability of  
53  
54 cataract surgery.

## Methods

This study was performed at the Department of Ophthalmology, First Affiliated Hospital, Zhejiang University, Hangzhou, China. All participants provided informed consent. The study was approved by the hospital's ethics committee and performed in accordance with the tenets of the Declaration of Helsinki.

Patients with age-related cataract undergoing phacoemulsification and IOL implantation in the right eye were invited to join this study. Patients who met the following criteria were included: (1) right-eye cataract with nuclear opalescence of grade 2 to 4 according to the Lens Opacities Classification System III scale (Chylack et al. 1993), (2) preoperative corneal astigmatism less than 2.0 D, (3) axial length of 22.0 to 26.0 mm. The exclusion criteria were: (1) high myopia (worse than -6.0 D) or high hyperopia (greater than +3.0 D), (2) ocular surface disorders (severe dry eye, significant Meibomian gland dysfunction, entropion, trichiasis, ectropion), (3) corneal diseases, glaucoma, uveitis and retinal diseases, (4) history of ocular surgery or trauma, (5) systematic diseases (diabetic mellitus, thyroid disease, autoimmune disease), (6) significant surgery-related complications, (7) incomplete follow-up data.

All patients received a complete routine ocular examination within 2 weeks before surgery, including slit-lamp biomicroscopy, intra-ocular pressure measurement, computerized refraction, uncorrected distance visual acuity,

1  
2  
3  
4 corrected distance visual acuity (CDVA), corneal endothelial cell count, ultra  
5  
6 sound A and B scan, and fundus photography. The follow-up time of 1 month  
7  
8 and 6 months was adopted.  
9

#### 10 11 12 13 14 *AS-OCT assessments*

15  
16  
17 The swept source AS-OCT (SS-1000 CASIA, Tomey Corp.) assessments  
18  
19 were performed within 2 weeks preoperatively and at 1 month and 6 months  
20  
21 postoperatively. The AS-OCT assessments were performed by one  
22  
23 experienced examiner (H.Q.). Patients were required to blink before each  
24  
25 measurement and keep their eyes open widely for sufficient exposure during  
26  
27 assessment. For both pre- and postoperative assessments, radial scans taken  
28  
29 at the corneal vertex were performed and patients were instructed to gaze at  
30  
31 the fixation target. For postoperative CCI assessments, radial scans taken  
32  
33 perpendicular to the CCI site were also performed and patients were instructed  
34  
35 to look at the opposite side of the CCI. Each assessment was repeated until  
36  
37 three usable measurements were acquired to ensure consistency.  
38  
39  
40  
41  
42  
43  
44

45  
46 Cross-sectional images of CCI were obtained and evaluated. The  
47  
48 architectural deformities of CCI were categorized (Figure 1): (1) endothelial gap,  
49  
50 (2) epithelial gap, (3) DMD and (4) wound misalignment. Incisions with either  
51  
52 endothelial gap, epithelial gap, DMD or misalignment were grouped as  
53  
54 defective incisions, the others were intact incisions. The following incision  
55  
56 parameters were measured using the package caliper tool of Tomey  
57  
58  
59  
60

1  
2  
3  
4 Measurement software (Tomey Corp.) and the abbreviations were used for  
5  
6 easy reading (Figure 2): (1) IL, (2) angle between incision and corneal  
7  
8 epithelium (incision entry angle, Angle-En), (3) angle between incision and  
9  
10 corneal endothelium (incision exit angle, Angle-Ex), (4) CT at incision entry (CT-  
11  
12 En), (5) CT at incision exit (CT-Ex), (6) the distance from incision entry to central  
13  
14 cornea (incision entry distance, Dis-En), (7) the distance from incision exit to  
15  
16 central cornea (incision exit distance, Dis-Ex). According to the CCI location,  
17  
18 CT at the corresponding position before surgery was measured using the  
19  
20 preoperative AS-OCT images. The discrepancy of CT at the CCI before and  
21  
22 after surgery was calculated.  
23  
24  
25  
26  
27  
28  
29  
30  
31

### 32 *Pentacam assessments*

34  
35 The Pentacam assessments were completed as described in our previous  
36  
37 work (He et al. 2019). Briefly, each patient received measurements  
38  
39 preoperatively and postoperatively at 1 month and 6 months, and the following  
40  
41 data were extracted: (1) keratometry of anterior and posterior cornea, (2)  
42  
43 magnitude and meridian of anterior and posterior corneal astigmatism, (3)  
44  
45 central corneal thickness (CCT), (4) corneal volume (CV), (5) coefficients of  
46  
47 Zernike polynomials up to 4th order at central 4 mm and 6 mm diameter zones  
48  
49 on total, anterior and posterior corneal surfaces. SIA vectors were calculated  
50  
51 with the method described by Alpíns (Alpíns & Goggin 2004). The mean  
52  
53 magnitudes of individual SIA vectors and the centroid values were reported.  
54  
55  
56  
57  
58  
59  
60

1  
2  
3  
4 The torque and flattening effect at the meridian of corneal incision were  
5  
6 analyzed. The root-mean-square (RMS) of total HOAs (tHOAs) through the 3rd  
7  
8 to 4th orders was calculated.  
9  
10

### 11 12 13 14 *Surgical procedures*

15  
16 All the cataract surgery was performed by one experienced surgeon (H.W.),  
17  
18 as described in our previous work (He et al. 2019). For all patients, a 2.2 mm  
19  
20 CCI was created at the 11 o'clock meridian and a 0.6 mm subsidiary incision  
21  
22 was made at 2 o'clock meridian using single-use steel blades. The surgery was  
23  
24 performed using the Centurion System (Alcon, Inc.). An Akreos MI 60 IOL was  
25  
26 implanted using the Hydroport PS27 injector system (Bausch + Lomb, Inc.).  
27  
28 Intraoperative parameters including total operation time, U/S total time and  
29  
30 cumulative dissipated energy were recorded.  
31  
32  
33  
34  
35  
36  
37  
38  
39  
40

### 41 *Statistical Analysis*

42  
43 The sample size was calculated using PASS version 15.0. Based on a  
44  
45 small-size retrospective pilot experiment, mean differences and standard  
46  
47 deviations of IL (mean diff. = 0.18 mm, SD = 0.24 mm), SIA (mean diff. = 0.13  
48  
49 D, SD = 0.17 D) and HOAs (mean diff. = 0.025  $\mu\text{m}$ , SD = 0.031  $\mu\text{m}$ ) were  
50  
51 obtained for sample size calculation. The n of defective incision group was  
52  
53 approximately 1.5 times that of intact incision group. Therefore, the group  
54  
55 allocation index was set as 1.5. A sample size of 80 eyes (32 eyes for intact  
56  
57  
58  
59  
60

1  
2  
3  
4 incision group and 48 eyes for defective incision group) yielded 90% power with  
5  
6 a type I error rate of 5%.  
7  
8

9 Statistical analysis was performed using SPSS software (version 22.0, IBM  
10 Corp.). A Kolmogorov-Smirnov test was used to test the normality of each data  
11 set. A Pearson chi-square test was used for categorical variables. The  
12 repeated-measures analysis of variance followed by Bonferroni post hoc test  
13 was applied to compare the preoperative data and postoperative data. For the  
14 within-group comparisons, a *P* value less than 0.05 was considered statistically  
15 significant.  
16  
17  
18  
19  
20  
21  
22  
23  
24  
25  
26

27 The Mann-Whitney U test was performed for group-wise comparisons. The  
28 Spearman's correlation analysis was performed to test the correlation between  
29 the CCI architecture parameters and corneal SIA & HOAs. To solve the  
30 multiple-testing issue, the false discovery rate (FDR) was applied for the group-  
31 wise comparisons and correlation analyses (Benjamini & Hochberg 1995). An  
32 FDR level less than 0.05 was considered statistically significant.

## 45 Results

46  
47  
48 Totally 361 eyes (272 patients) received cataract surgery during study  
49 period. Only right eyes were assessed, and hence 149 left eyes were excluded.  
50  
51 According to the inclusion and exclusion criteria, 129 eyes of 129 patients were  
52 included after preoperative examinations. Among them, 28 patients refused to  
53 participate, so that 101 eyes of 101 patients were enrolled in our observation.  
54  
55  
56  
57  
58  
59  
60

1  
2  
3  
4 Among the 101 patients, 9 patients failed to complete the follow-up. Finally, 92  
5  
6 eligible subjects (47 females and 45 males) were recruited. According to the  
7  
8 CCI features assessed by AS-OCT at 1 month postoperatively, 38 eyes were  
9  
10 categorized as the intact incision group and the remaining 54 eyes were the  
11  
12 defective incision group.  
13  
14  
15

16  
17 The clinical information of the intact and defective groups is listed in Table  
18  
19 1. The baseline clinical data of the two groups were similar (Table 1 and Table  
20  
21 S1).  
22  
23

24  
25 **(Insert Table 1 here)**  
26  
27  
28  
29

### 30 *CCI features assessments*

31  
32 The CCI features assessments at 1 month and 6 months postoperatively  
33  
34 are listed in Table 2. For the defective incision group at 1 month postoperatively,  
35  
36 59.3% had endothelial gap, 13.0% had DMD and 33.3% had wound  
37  
38 misalignment. No epithelial gap was observed. At 6 months, no DMD or  
39  
40 epithelial gap was observed, but 5 (9.3%) eyes showed endothelial gap and 20  
41  
42 (37.0%) eyes showed wound misalignment for the defective incision group. The  
43  
44 intact incision group had significant longer IL ( $P=.001$ , Mann-Whitney U test)  
45  
46 and smaller incision angles (Angle-En,  $P=.000$ ; Angle-Ex,  $P=.017$ ). No  
47  
48 difference was found between the two groups regarding the incision distances.  
49  
50  
51  
52  
53  
54

55  
56 At 1 month, CV was significantly increased in both two groups ( $P<.05$ ,  
57  
58 repeated-measures analysis of variance followed by Bonferroni post hoc test).  
59  
60

1  
2  
3  
4 At 6 months, no significant changes in CCT or CV were observed in  
5  
6 comparisons with preoperative values for both groups. The changes in CCT  
7  
8 and CV were similar between groups at each follow-up ( $P>.05$ ). At 1 month, the  
9  
10 defective group showed significant increase in CT-En and CT-Ex ( $P=.026$ ,  
11  
12  $P<.001$ , respectively), while the intact group only showed significant increase  
13  
14 in CT-Ex ( $P=.002$ ). The changes in CT-Ex for the defective incision group were  
15  
16 more pronounced ( $P<.001$ ) at 1 month. At 6 months, CT-En and CT-Ex were  
17  
18 similar to baseline for both groups, and no significant differences were observed  
19  
20 between groups (Table 2).  
21  
22  
23  
24  
25  
26  
27  
28  
29

### 30 *Corneal SIA analysis*

31  
32 The SIA-related parameters on the anterior and posterior corneal surface  
33  
34 showed no significant difference between the two groups after correction for  
35  
36 multiple comparisons (Table 2).  
37  
38  
39

40 **(Insert Table 2 here)**  
41  
42  
43  
44

### 45 *Corneal tHOAs analysis (Figure 3)*

46  
47 After multiple comparisons correction, both groups showed no significant  
48  
49 changes for total and anterior corneal tHOAs at postoperative 1 month and 6  
50  
51 months. The 4 mm posterior corneal tHOAs were slightly increased in the intact  
52  
53 incision group ( $P=.032$ ) at postoperative 1 month. The 6 mm posterior corneal  
54  
55 tHOAs were increased in both groups (intact incision group,  $P=.007$ ; defective  
56  
57  
58  
59  
60

1  
2  
3  
4 incision group,  $P<.001$ ) at postoperative 1 month. At 6 months, statistically  
5  
6 significant increase in the posterior corneal tHOAs over the 6 mm zone were  
7  
8 only observed for the defective incision group ( $P=.023$ ).  
9  
10

#### 11 12 13 14 *Corneal individual Zernike HOAs analysis*

15  
16  
17 **4 mm analytical zone (Figure 4).** For the total cornea, the spherical  
18  
19 aberration (SA) was significantly decreased (negative shift) in the two groups  
20  
21 ( $P<.05$ ), whereas significant changes in  $Z(3, -3)$  and  $Z(3, 3)$  terms were only  
22  
23 present in the defective incision group ( $P<.05$ ) at 1 month. For the anterior  
24  
25 corneal surface, significant changes in SA,  $Z(3, -3)$  and  $Z(3, 3)$  were only  
26  
27 present in the defective incision group ( $P<.05$ ) at 1 month. For the posterior  
28  
29 corneal surface, significant changes in  $Z(3, 3)$  terms were found in the defective  
30  
31 incision group ( $P=.038$ ) at 1 month. No changes in individual Zernike terms  
32  
33 were observed at 6 months.  
34  
35  
36  
37  
38  
39

40  
41 **6 mm analytical zone (Figure 5).** For the total cornea,  $Z(3,-1)$  showed  
42  
43 significant negative shift in both groups at 1 month and 6 months  
44  
45 postoperatively ( $P<.05$ ). The SA decreased in both groups at postoperative 1  
46  
47 month ( $P<.001$ ). At 6 months, the SA in defective incision group still had  
48  
49 significant difference compared with the preoperative value ( $P=.005$ ).  
50  
51 Significant changes in  $Z(3, -3)$  and  $Z(3, 3)$  terms were only found in the defective  
52  
53 incision group ( $P<.001$ ).  $Z(4, 4)$  was significantly increased in both groups  
54  
55 ( $P<.001$ ) at 1 month. For the anterior corneal surface, the SA was significantly  
56  
57  
58

2  
3  
4 decreased in both two groups ( $P<.001$ ) at 1 month. Significant changes in Z(3,  
5  
6 -3), Z(3, -1) and Z(3, 3) were found in the defective incision group ( $P<.001$ ) at  
7  
8  
9 1 month. Z(4, 4) was significantly increased in the two groups ( $P<.01$ ) at 1  
10  
11 month. No changes in anterior corneal Zernike terms were observed at 6  
12  
13 months. For the posterior corneal surface, significant changes in SA, Z(3, -1),  
14  
15 Z(3, 3), and Z(4, 4) were found for the defective incision group ( $P<.01$ ) at 1  
16  
17 month. Changes in SA and Z(3, -1) were also observed at 6 months for  
18  
19 defective incision group ( $P<.05$ ). The intact incision group presented significant  
20  
21 changes in Z(3,-1) and Z(4,-4) at postoperative 1 month ( $P<.01$ ).  
22

### 30 *Correlation analysis between SIA and CCI features (Table 3)*

31  
32 With an FDR level of 0.05, the cutoff for significant correlation between SIA  
33  
34 and CCI features was 0.0033. When 1 month postoperatively, for the intact  
35  
36 incision group, the anterior corneal SIA torque was positively correlated with  
37  
38 CT-En ( $P<.0033$ , Spearman's correlation analysis), while the anterior corneal  
39  
40 SIA flattening effect showed positive correlation with the CCT and CV variations  
41  
42 ( $P<.0033$ ). The posterior surface SIA flattening and absolute torque showed  
43  
44 weak positive correlation with incision angles and CT-Ex respectively ( $P<.0033$ ).  
45  
46 For the defective incision group 1 month postoperatively, the anterior corneal  
47  
48 SIA was significantly correlated to IL and Angle-En ( $P<.0033$ ). The posterior  
49  
50 surface flattening effect was positively correlated to IL and negatively correlated  
51  
52 to Dis-Ex ( $P<.0033$ ). The posterior torque showed negative correlation with IL  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3  
4 and positive correlation with Angle-Ex ( $P<.0033$ ).  
5

6  
7 At 6 months postoperatively, no significant correlation between SIA and  
8  
9 CCI features was found for the intact incision group. For the defective incision  
10  
11 group, IL still showed correlation with the anterior corneal SIA magnitude and  
12  
13 torque and posterior corneal flattening ( $P<.0033$ ). The Angle-En was correlated  
14  
15 with the anterior surface SIA magnitude and Angle-Ex was correlated with  
16  
17 posterior surface torque ( $P<.0033$ ).  
18  
19  
20

#### 27 *Correlation analysis between HOAs and CCI features*

28  
29 **4 mm analytical zone (Table 4).** With an FDR level of 0.05, the cutoff for  
30  
31 significant correlation between 4 mm corneal HOAs and CCI features was  
32  
33 0.0025. For the intact incision group at 1 month postoperatively, CCT showed  
34  
35 significant negative correlation with the posterior surface vertical coma  
36  
37 ( $P<.0025$ ). CT-Ex had close negative correlation with the posterior vertical  
38  
39 coma and SA ( $P<.0025$ ). IL was significantly negatively correlated to the total  
40  
41 corneal vertical coma ( $P<.0025$ ), while Angle-En had positive correlation with  
42  
43 total corneal vertical coma and vertical trefoil ( $P<.0025$ ). For the defective  
44  
45 incision group, both CT-En and CT-Ex showed correlation with several Zernike  
46  
47 aberrations, including the tHOAs, vertical coma, oblique trefoil and SA  
48  
49 ( $P<.0025$ ). IL was mainly negatively correlated to the total and anterior vertical  
50  
51 coma ( $P<.0025$ ). Angle-En presented positive correlation with the total and  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3  
4 anterior vertical coma ( $P<.0025$ ), whereas Angle-Ex was positively correlated  
5  
6 to the posterior oblique trefoil ( $P<.0025$ ). The Dis-Ex had significant positive  
7  
8 correlation with the posterior oblique trefoil ( $P<.0025$ ).  
9

10  
11  
12 **(Insert Table 4 here)**  
13

14 **6 mm analytical zone (Table 5).** With an FDR level of 0.05, the cutoff for  
15  
16 significant correlation between 6 mm corneal HOAs and CCI features was  
17  
18 0.0091. There were more HOAs parameters that significantly correlated with  
19  
20 CCI features considering the 6 mm analytical zone than the 4 mm analytical  
21  
22 zone. For the intact incision group 1 month postoperatively, CCT showed  
23  
24 negative correlation with the posterior oblique trefoil ( $P<.0091$ ), while CV was  
25  
26 negatively correlated to the anterior surface SA and posterior oblique trefoil  
27  
28 ( $P<.0091$ ). Significant correlation between CT-En and the anterior surface  
29  
30 tHOAs and vertical/horizontal coma changes was observed, whereas CT-Ex  
31  
32 was strongly correlated to the anterior and posterior Zernike terms ( $P<.0091$ ).  
33  
34 IL was positively correlated to the posterior surface tHOAs and negatively  
35  
36 correlated to the total vertical trefoil ( $P<.0091$ ). Angle-En exhibited negative  
37  
38 correlation with the total and anterior corneal tHOAs, and positive correlation  
39  
40 with total and anterior corneal vertical coma and trefoil terms ( $P<.0091$ ). There  
41  
42 was obvious positive correlation between Dis-En and the total and anterior  
43  
44 vertical coma, while Dis-Ex was positively correlated to the total, anterior and  
45  
46 posterior vertical coma and the total SA ( $P<.0091$ ). For the defective incision  
47  
48 group, significant negative correlation of CV with the total and anterior vertical  
49  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3  
4 coma was observed ( $P<.0091$ ). CT-En and CT-Ex were negatively correlated  
5  
6 to vertical coma ( $P<.0091$ ) and CT-Ex was also negatively correlated to the  
7  
8 total and anterior oblique trefoil and the posterior SA ( $P<.0091$ ). IL presented  
9  
10 correlation with the posterior tHOAs as well as the total and anterior vertical  
11  
12 trefoil and horizontal coma ( $P<.0091$ ). Angle-Ex was correlated to the total and  
13  
14 anterior surface coma and posterior surface oblique trefoil ( $P<.0091$ ).  
15  
16 Correlation of Dis-En with tHOAs, total and anterior surface oblique trefoil and  
17  
18 posterior surface SA reached significance ( $P<.0091$ ), while Dis-Ex was  
19  
20 negatively correlated to posterior tHOAs, and positively correlated to total and  
21  
22 anterior oblique trefoil and the posterior vertical coma ( $P<.0091$ ).

## 35 **Discussion**

### 36 *CCI features analysis*

37  
38  
39  
40 At 1 month postoperatively, approximately 60% of patients exhibited  
41  
42 defective incision features of endothelial gap, DMD or wound misalignment,  
43  
44 indicating a prolonged wound healing (Figure 1). Previous studies have  
45  
46 reported a range of incidences for patients who had defective incisions. This  
47  
48 might be due to the discrepancies in surgical techniques, including  
49  
50 femtosecond laser-created CCI (Alio et al. 2013; Grewal & Basti 2014; Chaves  
51  
52 et al. 2019), incision width (Li et al. 2011; Li et al. 2018), stromal hydration  
53  
54 (Fukuda et al. 2011; Bang et al. 2015), postoperative drug usage (Choi et al.  
55  
56  
57  
58  
59  
60

1  
2  
3  
4 2016) and measuring principles.  
5

6 The frequency of the DMD and wound misalignment at 1 month was similar  
7  
8 to previous studies (Wang et al. 2012; Li et al. 2018; Rodrigues et al. 2019). At  
9  
10 6 months postoperatively, the features of defective CCI disappeared in most  
11  
12 subjects of the defective incision group, while some subjects still showed wound  
13  
14 misalignment (37%) and endothelial gap (9%) (Table 2). It was noticeable that  
15  
16 at 6 months, the frequency of endothelial gap and DMD significantly declined,  
17  
18 whereas the frequency of wound misalignment was slightly increased,  
19  
20 indicating the long-term existence of wound misalignment as reported by  
21  
22 previous studies (Choi et al. 2016; Li et al. 2018). Wound misalignment was  
23  
24 associated with collagen deposits and incision remodeling (Li et al. 2018). The  
25  
26 increased incidence of wound misalignment might be due to the healing effect  
27  
28 of incisions with endothelial gap and DMD. The changing profile of endothelial  
29  
30 gap, DMD and wound misalignment from 1 month to 6 months demonstrated  
31  
32 the recovering and remodeling process of CCI.  
33  
34  
35  
36  
37  
38  
39  
40  
41  
42

43 Our data also revealed that the endothelial gap was much more common  
44  
45 than the epithelial gap (Vasavada et al. 2013; Lee et al. 2014; Rodrigues et al.  
46  
47 2019). This may be due to the rapid healing of epithelium side compared with  
48  
49 the endothelium side which was directly exposed to the inflammatory  
50  
51 environment in aqueous humor. This further supported our previous finding that  
52  
53 the changes in the posterior corneal HOAs were more pronounced after surgery  
54  
55 (He et al. 2019).  
56  
57  
58  
59  
60

1  
2  
3  
4 The defective incision group had significantly shorter incision length and  
5  
6 larger incision entry/exit angles, suggesting the shorter incision is more likely to  
7  
8 be associated with the occurrence of the incision deformities. Hayashi et al.  
9  
10 (Hayashi et al. 2018) also found a higher rate of DMD in short CCIs. The longer  
11  
12 incisions require less hydration sealing and help incision healing (Fine et al.  
13  
14 2007), but may increase the chance of tear during the handpiece maneuver  
15  
16 and IOL injection. In this study, we chose the 1.8 mm MI 60 IOL to minimize the  
17  
18 influence of incision tear at the IOL implantation step. Our data suggests that  
19  
20 longer incisions with smaller angles were beneficial to the incision integrity.  
21  
22  
23  
24  
25

26  
27 The changes in CV or CT indicated manifest cornea edema was present  
28  
29 until 1 month postoperatively, which was similar to the previous studies (Li et  
30  
31 al. 2011; Li et al. 2018). The increasing CT-Ex in both groups at 1 month  
32  
33 demonstrated the retarded healing of the endothelium surface. Moreover, the  
34  
35 retarded dissipation of cornea edema in the defective incision suggested the  
36  
37 influence of incision deformities in the corneal wound healing (Table 2). At 6  
38  
39 months, CV and CT of both two groups returned to baseline level, suggesting  
40  
41 the dissipation of corneal edema at both central cornea and CCI sites.  
42  
43  
44  
45  
46  
47  
48  
49  
50

#### 51 *SIA and CCI features*

52  
53 Among the SIA indices, no significant differences between the defective  
54  
55 and intact incision groups were observed at 1 month and 6 months  
56  
57 postoperatively (FDR- $P > .05$ ) (Table 2). The results indicated the little impact of  
58  
59  
60

1  
2  
3  
4 CCI's integrity on SIA, as the 2.2 mm incision was thought not to cause  
5  
6 significant SIA (Wang et al. 2009).  
7  
8

9 For the intact incision, some CCI features (CCT, CV and CT-En) showed  
10  
11 correlation with the anterior surface flattening effect and torque at 1 month, but  
12  
13 no significant correlation was observed at 6 months, indicating that the impact  
14  
15 of corneal edema on the anterior surface SIA persisted until 1 month and  
16  
17 declined at 6 months due to the dissipation of edema. For the defective incision,  
18  
19 IL seemed to be the most important parameter influencing SIA. The IL showed  
20  
21 positive correlation with the SIA magnitude at postoperative 1 month and 6  
22  
23 months. It was noticeable that the IL always exhibited reverse  $r$  values (positive  
24  
25 correlation) when compared with the incision angles (negative correlation). Our  
26  
27 data suggested that longer CCI coupled with smaller incision angles might  
28  
29 cause more SIA on both anterior and posterior surfaces, especially in the  
30  
31 defective incision group (Table 3).  
32  
33  
34  
35  
36  
37  
38  
39

40 Ferreira et al.(Ferreira et al. 2018) found less SIA in the femtosecond laser  
41  
42 created incision than the manually 2.4 mm incisions. Zhu et al.(Zhu et al. 2017)  
43  
44 found significant correlation between the SIA and distance from the incision  
45  
46 entry to central cornea. Choi et al.'s work standardized the CCI deformities by  
47  
48 wound deformity scoring and found positive correlations between SIA and  
49  
50 wound instability (Choi et al. 2016). Our results were in agreement with the  
51  
52 previous studies (Wilczynski et al. 2016; Hayashi et al. 2018; Sonmez & Karaca  
53  
54 2018) and we further evaluated the correlation between the CCI features and  
55  
56  
57  
58  
59  
60

9

### 10 11 *Total HOAs and CCI features* 12

13  
14 There are few studies regarding the relation between the CCI architecture  
15 features and corneal HOAs. Alio et al.(Alio et al. 2013) described the  
16 morphological changes of CCI after the femtosecond laser-assisted cataract  
17 surgery and found no significant changes in the corneal HOAs. Only slight  
18 increase of posterior corneal tHOAs over 4 mm zone was observed in the intact  
19 incision group ( $P=.032$ ), indicating that the 4 mm tHOAs were less affected  
20 (Figure 3A). The changes in the 6 mm corneal tHOAs were more pronounced.  
21 Mild increase of the total corneal tHOAs over 6 mm zone at 1 month was  
22 observed in the defective incision group ( $P=.084$ ), while the posterior corneal  
23 tHOAs changes over 6 mm zone were significant for both groups at 1 month,  
24 but at 6 months, the significance level was only observed in the defective  
25 incision group (Figure 3B). These results indicated the influence of incision  
26 deformities in the mid-peripheral and posterior corneal tHOAs.  
27  
28  
29  
30  
31  
32  
33  
34  
35  
36  
37  
38  
39  
40  
41  
42  
43  
44  
45  
46  
47

48 The more pronounced and longer-standing posterior HOAs changes  
49 suggested the importance of the posterior corneal surface for the optical quality  
50 postoperatively. It is reasonable to speculate that changes in total and posterior  
51 corneal HOAs at 1 month were associated with significant corneal edema at  
52 central cornea and incision site. However, changes in posterior corneal HOAs  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3  
4 at 6 months ought to be related to the wound deformities like misalignment  
5  
6 rather than corneal edema, as corneal edema should have dissipated at 6  
7  
8 months. In our subjects, the wound misalignment always occurred at incision  
9  
10 exit, hence the posterior corneal HOAs were apt to be affected (Figure 3).  
11  
12  
13  
14  
15  
16

### 17 *Individual HOAs and CCI features*

18  
19 Previous studies have found the changes in trefoil after surgery (Tong et al.  
20  
21 2008; Can et al. 2012; Yu et al. 2016). We found remarkable changes in vertical  
22  
23 and oblique trefoil terms over the 4 mm and 6 mm zones in the defective incision  
24  
25 group at 1 month. The CCI deformities in early postoperative stage might alter  
26  
27 the corneal contour and induce more trefoil changes, as no evident changes in  
28  
29 trefoil were found in the intact incision group. At late stage of 6 months  
30  
31 postoperatively, no such significant changes were observed. The negative shift  
32  
33 of SA in both incisions can be ascribed to the effect of corneal flattening due to  
34  
35 the surgically induced stroma edema in the mid-peripheral corneal zone at 1  
36  
37 month. At 6 months, the changes in posterior SA over 6 mm zone were still  
38  
39 observed in the defective incision group, indicating a long-term effect of CCI on  
40  
41 posterior SA. Similarly, the 6 mm zone vertical coma on the total and posterior  
42  
43 surfaces also showed negative shift for both incision groups. The vertical coma  
44  
45 value is generally positive, due to the steeper contour of upper corneal zone  
46  
47 compared with the lower corneal zone. The negative shift of vertical coma can  
48  
49 also be ascribed to the superiorly located CCI (Song et al. 2015), which mainly  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3  
4 caused corneal edema and flattening of the corneal curvature in the upper zone.  
5  
6 Such changes persisted until 6 months in our subjects. Besides, no evident  
7  
8 changes in horizontal coma also support this point (Figures 4 and 5).  
9  
10

11  
12 According to the HOAs analysis described above, the typical Zernike terms  
13  
14 including coma, trefoil and SA were selected for the correlation analysis in order  
15  
16 to evaluate the potential role of the CCI parameters in the corneal HOAs  
17  
18 changes at postoperative 1 month. The correlation results between CCI  
19  
20 features and HOAs at 6 months became much less significant and exhibited  
21  
22 the random effects (data not shown), indicating the diminished significant  
23  
24 impact of corneal incision on the HOAs. In general, the 4 mm HOAs showed  
25  
26 less significant correlation with the CCI parameters than the 6 mm HOAs,  
27  
28 suggesting less effect of CCI features on central optical quality. These results  
29  
30 coincided with the observation that no significant difference in the postoperative  
31  
32 central vision (CDVA) between the two groups (Table 1).  
33  
34  
35  
36  
37  
38  
39

40  
41 The vertical coma showed strong correlation with multiple CCI features,  
42  
43 especially the CT, IL and incision angles. As described above, the superior CCI  
44  
45 caused the asymmetrical cornea contour changes along the vertical meridian,  
46  
47 hence the vertical coma was associated with the specific relevant CCI  
48  
49 parameters. The 6 mm vertical coma was significantly associated with the Dis-  
50  
51 En and Dis-Ex for the intact incision, but was less affected by Dis-En and Dis-  
52  
53 Ex for the defective incision (Tables 4 and 5). For defective incision group, the  
54  
55 vertical coma may be affected by other factors including corneal edema,  
56  
57  
58  
59  
60

1  
2  
3  
4 incision gap and DMD. These factors may have stronger effect in coma  
5  
6 changes in cases of defective incisions.  
7

8  
9       Similar to SIA, the corneal tHOAs changes were positively correlated with  
10  
11 IL and negatively correlated with incision angles. A longer IL tends to be more  
12  
13 intact and well-sealing than a shorter one (Fine et al. 2007), but can enlarge the  
14  
15 incision area and degrade the corneal optical quality. The shorter IL, coupled  
16  
17 with larger incision angles, helps to reduce the HOAs or SIA. However, it was  
18  
19 noticeable that the mean IL in the defective incision group ( $1.42\pm 0.19$  mm) was  
20  
21 significantly shorter than that in the intact incision group ( $1.56\pm 0.22$  mm).  
22  
23 Except for the risk of leakage, a short IL requires more hydration sealing and  
24  
25 was more likely to cause incisions deformities and stromal edema at incision  
26  
27 site, which were related to higher corneal HOAs and SIA as mentioned above  
28  
29 (Tables 2, 3 and Figure 3). Thus, the IL has the dual effect on postoperative  
30  
31 corneal HOAs and SIA.  
32  
33  
34  
35  
36  
37  
38  
39

40       The Dis-En and Dis-Ex are less important for the central 4 mm HOAs, but  
41  
42 can influence the 6 mm HOAs changes especially in defective incision group  
43  
44 (Table 5). In this study, the superiorly located incisions (at 11 o'clock meridian)  
45  
46 were nearer to the cornea centroid and the effects on corneal optical quality  
47  
48 should be more prominent when compared with the temporal incisions. Further  
49  
50 investigations are necessary to determine the optimal incision parameters such  
51  
52 as IL and CCI location.  
53  
54  
55  
56  
57

58       Taken together, this study evaluated the CCI features after 2.2 mm incision  
59  
60

1  
2  
3  
4 cataract surgery and found that the CCI deformities induced more postoperative  
5  
6 corneal HOAs changes. Our results indicated that IL combined with Angle-  
7  
8 En/Ex was closely related to the CCI integrity and had significant effects on the  
9  
10 SIA and corneal HOAs changes at 1 month. At 6 months postoperatively, the  
11  
12 effects of CCI were still present, although became obviously minor. Future  
13  
14 studies involving more standardized parameters, including bi- or tri-planar CCI  
15  
16 created by femtosecond laser, multiple CCI sizes and positions, would be  
17  
18 clinically useful.

HOAs = higher-order aberrations; CCI = clear corneal incision; CCT = central corneal thickness; CV = corneal volume; CT-En = corneal thickness at incision entry; CT-Ex = corneal thickness at incision exit; IL = incision length; Angle-En = angle between incision and corneal epithelium; Angle-Ex = angle between incision and corneal endothelium; Dis-En = the distance from incision entry to central cornea; Dis-Ex = the distance from incision exit to central cornea; SA = spherical aberration

\*Significant ( $P < .0091$ ) after correction for multiple testing ( $n=324$ ) based on false discovery rate (FDR)

**Table S1** Preoperative corneal HOAs data by CCI integrity.
