## Proposing Researcher Brand Equity Index in Hospitality and Tourism

### Abstract

**Purpose:** This study proposes a holistic model to rank and evaluate researchers' performance.

This holistic model is developed by focusing on brand equity, which includes three components: perceived quality, brand image, and brand loyalty.

**Design/methodology/approach:** To show how the model works, two pseudo cases are presented.

**Findings:** This model encourages researchers to conduct more interdisciplinary research and collaborate with researchers from diverse backgrounds. The model allows researchers to strengthen their brand equity score or performance, since it includes publication attributes identified by researchers in the publication processes.

**Practical Implications:** The model is applicable not only to the fields of hospitality and tourism but also other to disciplines.

**Originality/Value:** As one of the first study in the field, this research introduces a holistic model to rank and evaluate researchers' performance.

*Keywords:* individual ranking, performance evaluation, brand equity, tourism, hospitality

## INTRODUCTION

The main purpose of this study is to propose a holistic individual ranking model in hospitality and tourism research called the Researcher's Brand Equity Index. Ranking of researchers has always been an interesting field of inquiry for researchers and institutions since it helps them to evaluate their position within academic communities. There are a number of studies ranking authors or researchers in various disciplines (Bouyssou & Marchant, 2016; Li, Wang, Zhang, Lei, Ma, & Chen, 2014; Marchant, 2009; Zhou, Orshanskiy, Zha, & Giles, 2007). As shown in the journal ranking literature (Koseoglu, 2018), research on ranking individuals has generated its own literature and academic community due to the importance of individual rankings on researchers' performance appraisals and headhunting for institutions, government agencies, and publishers. These studies have focused on developing new ranking models, experimenting with these models in different disciplines, or discussing the usefulness of these models (Law, 2017; Rickman & Winters, 2016; Yang, Hong, Yin, & Davison, 2015).

The existing ranking models have two main constructs. They are research quantity and research quality (Dev, Parsa, Parsa, & Bujisic, 2015). Research quantity is an objective measure that includes the counting of publications based on the contribution of an author. In multi-authored publications, this contribution has been identified as the number of publications or fractional scores (Furrer, Thomas, & Goussevskaia, 2008; Koseoglu, Yildiz, & Ciftci, 2018). Research quality is a less objective measure than research quantity, yet it is still used to rank and evaluate researchers. To measure research quality, the number of citations and/or indexes derived from citations has been used in individual rankings. However, these models neglect to measure an author's contribution based on structure of collaboration, type of contribution, methodology, and funding for the work. Additionally, they do not provide a holistic perspective for the ranking

1  
2  
3 and performance appraisal of researchers. To meet this need for a holistic ranking, this study  
4  
5 proposes a new approach called the Researcher's Brand Equity Index (RBEI), which borrows the  
6  
7 term "brand equity" from the field of business and management. The main logic behind this is  
8  
9 that all researchers generate their own brand, which impacts both their career path and the  
10  
11 position of the institutions where they have worked. Therefore, measurement of the brand equity  
12  
13 (Aaker, 1996) of a researcher may help develop a holistic individual ranking model that can be  
14  
15 beneficial for researchers and institutions. The following section provides an overview of the  
16  
17 current approaches to individual rankings. The next section explains the proposed model using  
18  
19 the RBEI approach. The operationalization of the model is then presented and discussed. Finally,  
20  
21 conclusions and suggestions for future studies are provided.

## 26 **LITERATURE REVIEW**

### 27 **Overview of Individual Ranking Models**

28  
29  
30  
31 Researchers and institutions have developed models to rank and evaluate the performance  
32  
33 of individuals by considering mainly publication numbers or contribution level (quantity) of  
34  
35 researchers, the quality of published articles, or a combination of these two perspectives.  
36  
37 Therefore, three approaches—quantity-based models, quality-based models, and hybrid  
38  
39 models—emerge in the literature and in practice (Dev et al., 2015; Law, 2017).  
40  
41

42 *Quantity-based models:* The main metric in these models is publication count. There are  
43  
44 two types of quantity-based models to rank researchers in the literature. The first model is based  
45  
46 on publication numbers, or researchers' appearance in a given period (Law, 2017). The second is  
47  
48 based on scores calculated by authorship order (Furrer et al., 2008). The quantity-based models  
49  
50 are simple and commonly used in individual rankings (Law, 2017) or performance appraisals of  
51  
52 faculty's research performance. These methods may be objective, but they do not illustrate a  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 clear picture of the influence and impact researchers generate in the literature and/or academic  
4 communities. Based on the present study's authors' experience, these quantity-based methods  
5 are used by many institutions to evaluate faculty's research performance. However, in the  
6 practice of performance appraisal of researchers, formal guidelines established by an institution  
7 can improve objectivity. If institutions do not provide formal guidelines for this process, the  
8 subjectivity increases, and the methods become questionable. This may influence levels of  
9 satisfaction among researchers. Regardless, these quantify-based methods ignore how  
10 researchers are influential and create an impact, and are therefore not holistic in their approach.

11  
12 *Quality-based models:* In the individual ranking literature or performance appraisal of  
13 researchers, the determination of the quality of a publication is unclear. A publication's impact,  
14 often used to measure quality, is determined mainly by two indicators: citations numbers (Adkins  
15 & Budd, 2006) and/or journal impact factors (Amin & Mabe, 2000). However, these two  
16 indicators are not robust enough to determine the quality of publications since they are subject to  
17 bias (Law & Chon 2007). By considering Law's (2017) comments on the uselessness of  
18 individual ranking models, the present study offers that the quality of a publication should be  
19 gauged with three main indicators: authorship structure, methodological process, and impact of  
20 publication.

21  
22 Authorship structure is related to the group of authors themselves, since international  
23 collaboration in the publication (Van Raan, 1998), disciplinary diversity of authors (Barjak &  
24 Robinson, 2008), and gender of authors (Nunkoo, Hall, & Ladsawut, 2017) are highly influential  
25 on the quality of output. Methodological process addresses what procedure or methods are  
26 applied in the study, since each method (experimental, conceptual studies, mixed methods,  
27 traditional qualitative or quantitative, case studies, and review studies) requires different efforts  
28

1  
2  
3 to accomplish (Law, 2017). Impact of publication represents the quality of publishing based on  
4  
5 impact-factor metrics. Impact factors are measured primarily by the number times a work has  
6  
7 been cited. There are many approaches to calculate the number of citations as impact factors of  
8  
9 publishing. For example, Journal Citation Report and Scopus Journal Metrics are commonly  
10  
11 used.  
12  
13

14  
15 *Hybrid models:* As shown in Figure 1, researchers have developed models to eliminate  
16  
17 bias in the quantity-based and quality-based models. They include both quantity—number of  
18  
19 publications—and quality metrics—H-index (Hirsch, 2005), G-index (Egghe, 2006), M-Quotient  
20  
21 (Thompson, Callen, & Nahatta, 2006), EM-index (Bihari & Tripathi, 2017)—or some variations  
22  
23 of these metrics (Btista, Campitelli, Konouchi, & Martinex, 2006; Harzing & van der Wal,  
24  
25 2008). These indexes are based on publication numbers and citations. Additionally, authorship  
26  
27 network metrics are used to rank individuals. These metrics show the contributions and  
28  
29 relationships of researchers within a given publication (Law, 2017). In practice, institutions  
30  
31 commonly use both quantity- and quality-based approaches, along with peer reviews.  
32  
33  
34

36 -----  
37  
38 Insert Figure 1 about here  
39  
40 -----  
41

42  
43 In the literature, there are several studies (Park, Phillips, Canter, & Abbott, 2011;  
44  
45 Rutherford & Samenfink, 1992; Ryan, 2005; Samenfink & Rutherford, 2002; Ye, Li, & Law,  
46  
47 2013; Zhang 2015; Zhang, Lan, Qi, & Wu, 2017; Zhao & Ritchie, 2007) that rank researchers in  
48  
49 the fields of hospitality and tourism. These studies use the same indicators considered in  
50  
51 previous studies conducted in other disciplines or fields. Recently, Dev et al. (2015) introduced a  
52  
53 model to assess faculty productivity. They considered four indicators: number of citations as  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 quality of research output, number of publications as quantity of research output, citations per  
4 publication as consistency of quality research output, and citations per publication per year over  
5 an extended period as longevity of quality research. This model works as an aggregate of the  
6 average of ranking for these four indicators. Although Dev et al. (2015) stated that the model is  
7 easy, effective, and adaptable and that objectivity was maintained during its application, Law  
8 (2017) stated that “a major drawback of this assessment method is that although a scholar has left  
9 academia, the articles authored by this scholar will continue to receive citations, thereby leading  
10 to inaccurate results when comparisons are made with currently active scholars” (p. 393).

11  
12 All of these methods are indeed complementary, rather than alternatives to rank or  
13 evaluate the performance of individuals. However, they can produce questionable results because  
14 they lack subjectivity, are not holistic, are discipline specific, and ignore the longevity of an  
15 individual’s research life (Dev et al. 2015; Law, 2017). Therefore, the main goal of this present  
16 article is not to compare the advantages and disadvantages of the existing models but rather to  
17 introduce a holistic model minimizing subjectivity and discipline specifics and considering the  
18 longevity of individuals’ research life. As researchers create their own brand, the main question  
19 is how to measure the value of this brand. Addressing this question may help us to develop a  
20 holistic individual ranking model by increasing objectivity. This effort relies on the concept of  
21 brand equity as a marketing term, which is used to measure a brand’s value in the market (Aaker,  
22 1996).

### 23 **Brand Equity**

24 Brand equity is “a set of brand assets and liabilities linked to a brand, its name, and symbol,  
25 which add to or subtract from the value provided by a product or service to a firm and/or to that  
26 firm’s customers” (Aaker, 1991, p. 15). Several different perspectives exist to measure brand  
27  
28  
29  
30

54  
55  
56  
57  
58  
59  
60

1  
2  
3 equity. For example, Aaker (1991) considered four components including brand loyalty, brand  
4 awareness, brand association, and perceived quality. Keller (1993) used brand awareness and  
5 brand image as components of brand knowledge, which is accepted as brand equity. Lassar et al.  
6 (1995) highlighted five components of brand equity: performance, social image, value,  
7 attachment, and trustworthiness. Kim, Kim, and An (2003) addressed brand equity with brand  
8 loyalty, brand awareness, perceived quality, and brand image. As shown in the literature, there is  
9 not a consensus of how to measure brand equity. Therefore, for the present study, the brand  
10 equity of a researcher may be measured with perceived quality, brand image, and brand loyalty  
11 since the other components—brand association and brand awareness—are implicitly considered  
12 in brand perceived quality and brand loyalty, respectively (Chahal & Bala, 2012). Each of these  
13 components is discussed in more detail in the following section.

## 28 **METHODOLOGY**

### 29 **Proposed Researcher's Brand Equity Index**

30  
31 This study proposes a new model to rank and evaluate individual's research performance.  
32  
33 This is a holistic model that can increase objectivity in the ranking and performance appraisal by  
34 extending metrics. This model is called Researcher's Brand Equity Index (RBEI). The proposed  
35 RBEI model includes four components, including perceived quality, brand loyalty, brand image,  
36 and longevity of individuals' research life. Perceived quality is related to a customer's overall  
37 perception of the quality of a product or services (Chahal & Bala, 2012). In the RBEI model it is  
38 defined as publication attributes (PA), including authorship structure, methodology, and impact  
39 of publication. Brand loyalty refers to the willingness of a customer to re-buy products and  
40 services (Chahal & Bala, 2012). In this model it is accepted as the number of times a publication  
41 has been cited (CNpP) of a researcher, since this number may indicate how widely accepted the  
42  
43

1  
2  
3 studies of this researcher are. Brand image is defined as “the consumers’ perception of a brand as  
4 reflected by the brand associations held in their memory” (Chahal & Bala, 2012, p. 347). To  
5  
6 measure this component, the RBEI model considers the number of the researcher’s official  
7  
8 connections. In other words, the number of co-authors (CoN) of a researcher is considered their  
9  
10 brand image, since the collaboration number may generate greater interaction as image among  
11  
12 collaborators and readers of researchers’ studies. Longevity of an individual’s research life (LR)  
13  
14 is calculated as the difference between the time of a researcher’s first publication and the present  
15  
16 (or otherwise determined end point). The RBEI can be decomposed as follows:  
17  
18  
19

$$RBEI = \frac{CNpP * CoN * PA}{LR}$$

20  
21  
22  
23  
24  
25 where CNpP is the researcher’s brand loyalty, CoN is the researcher’s image, PA is  
26  
27 perceived quality of a researcher’s publications, and LR is the longevity of an individual’s  
28  
29 research life.  
30  
31

32 To show how the model works, a pseudo-case method is used because researchers’  
33  
34 information in databases such as ORCID, SCOPUS, Google Scholar Analytics, Web of Science,  
35  
36 and others is limited. Using the information from these databases may skew the results.  
37  
38

### 39 **Operationalizing RBEI**

40  
41 To first implement the model, institutions or researchers should decide which  
42  
43 publications they will include. While one way is to include all publications, institutions or  
44  
45 researchers may want to limit the publications based on the goal of ranking and/or evaluation.  
46  
47 For example, while refereed articles may be chosen, books, conference papers, and book  
48  
49 chapters might not be included in the model. After deciding this, the model can be constructed  
50  
51 with the following components.  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 *Longevity of individuals' research life (LR)*  
4

5 *LR* is the difference between the time of a researcher's first publication among the selected  
6  
7 publications and the current time (otherwise determined end point). RBEI can be calculated as  
8  
9 per day, month, or year.  
10  
11  
12

13  
14 *Citation Number per Publication of a Researcher (CNpP) as the researcher's brand loyalty*  
15

16  
17 The model obtains *CNpP* by dividing the total number of citations for the selected publications  
18  
19 of the researcher by total publication numbers. To increase the objectivity and to standardize  
20  
21 ranking or evaluation, institutions or researchers should select one database (e.g., ORCID,  
22  
23 SCOPUS, Google Scholar Analytics, Mendeley, Web of Science) to obtain the citation number  
24  
25 of the researcher. The *CNpP* can be decomposed as follows:  
26  
27

$$28 \quad CNpP = \frac{\text{Total citation numbers}}{\text{Total publication number}}$$

29  
30  
31  
32  
33

34 *Co-authors' numbers (CoN) of a researcher as researcher's brand image*  
35

36  
37 To measure *CoN*, we should count the number of co-authors in the selected publications. If the  
38  
39 researcher collaborates with a researcher more than once it must be counted as one credit.  
40  
41  
42

43 *Publication attributes (PA) as perceived quality*  
44

45  
46 Before calculating *PA*, institutions or researchers should decide how they treat publications.  
47  
48 They should assign credits for each publication type (PT) selected at the beginning to establish  
49  
50 the model. There are many ways to assign credit for publications. One example is presented  
51  
52 below (Table 1). Institutions and researchers may create similar tables by considering their goals.  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 For example, while some institutions may place a high value on books, others may put greater  
4 value on peer-reviewed journal articles.  
5  
6  
7  
8  
9

10 -----  
11  
12  
13 Insert Table 1 about here  
14  
15  
16 -----

17  
18 To calculate PA, this model includes three sub-components: authorship structure, methodological  
19 process, and impact of publishing. A description of these sub-components follows. These  
20 calculations should be repeated for each publication, then total PA should be calculated.  
21  
22  
23

24 A- Authorship structure has several dimensions:

- 25  
26  
27 1- Contribution level of researcher (CLR) represents how much a researcher contributes to  
28 the co-authored publication. There are two primary ways to calculate CLR. The first is to  
29 treat all researchers equally. For example, if there are four authors in a publication, the  
30 CLR for each author is 0.25 (1/4). The second method is to create a weighted matrix  
31 based on the number and order of a publication's authors. An example matrix is  
32 presented in Table 2. However, institutions and researchers have flexibility to create this  
33 table to meet their goals. For example, in China and other countries, it is common to  
34 place a high value on the corresponding author in their performance evaluation process.  
35  
36  
37  
38  
39  
40  
41  
42  
43  
44  
45  
46  
47  
48 -----

49  
50  
51 Insert Table 2 about here  
52  
53 -----  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 2- Internationalization of publication team (IPT) considers whether there is at least one  
4 international co-author in co-authored publications. The main reason for this value is that  
5 internationally co-authored publications receive more citations than nationally co-  
6 authored publications or single publications, so act (in)directly as a reflection of quality  
7 (Nguyen, Ho-Le, & Le, 2017). Table 3 presents an example of the IPT calculation when  
8 there are three authors: two or more authors from one institution and from one country,  
9 two or more authors from at least two different institutions from one country, and two or  
10 more authors from two or more institutions and two or more countries (Koseoglu,  
11 Okumus, Putra, Yildiz, & Dogan, 2017).

22 -----  
23  
24  
25  
26 Insert Table 3 about here  
27  
28 -----  
29

30  
31 3- Disciplinary background of the publication team (DBPT) reflects whether there is at least  
32 one team member from a different disciplinary background. In other words,  
33 multidisciplinary diversity on a research team is an important indicator of the quality of  
34 the publication (Okumus, van Niekerk, Koseoglu, & Bilgihan, 2018). Therefore, if there  
35 is at least one team member from a different discipline, such as law, the model will give  
36 one credit for those team members. If there are no differences among authors'  
37 disciplinary backgrounds, the model will not assign any credit.  
38  
39  
40  
41  
42  
43  
44  
45  
46  
47 4- Gender difference in the publication team (GDPT) is considered in this model since the  
48 role of gender in collaboration is impactful on the quality of the publication (Kyvik &  
49 Teigen, 1996; Lee & Bozeman, 2005; Melin, 2000; Myers, 1991). This is also important  
50 to encourage collaboration between genders to increase the representation of females in  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 academic research. In this model, if the publication is coauthored between at least one  
4 male and one female, the model will assign one credit for the team members. If there is  
5 no collaboration among different genders in the publication, the model will not assign  
6 any credit.  
7  
8  
9  
10  
11

12 5- Granted publication (GP) is valued in the model since granted projects have a robust  
13 process to generate publications. This process is influential in the quality of the  
14 publication. If the publication indicates that it is generated from a granted project, the  
15 model will assign one credit for the team members. If the publication does not indicate  
16 that it is grant funded, the model will not assign any credit.  
17  
18  
19  
20  
21  
22  
23

24 B- Methodological process (MP): The data collection process for each publication may not  
25 be the same. For example, while researchers need considerable time for an experimental  
26 design, they may need less time for a case study of a specific business organization.  
27  
28 Therefore, they should not be treated equally in the ranking of individuals or in a  
29 performance appraisal, as indicated by Law (2017). To calculate MP, a weighted system  
30 should be used. Table 4 presents an example of methodological processes and their  
31 weights. Institutions and researchers are flexible to create this table to suit their goals.

46  
47 C- Impact of publishing (IP): Each published work generates a different impact in their field.  
48  
49 This impact level shows the quality of a publication (Elliott, 2014; Garfield, 2003; Saha,  
50 Saint, & Christakis, 2003). However, assessing the impact of a published work is  
51 complicated. A few companies (e.g., Clarivate Analytics, SCOPUS) release impact  
52  
53  
54  
55  
56  
57  
58  
59  
60

factors of journals that are accepted in their databases. In this model, institutions and researchers are free to choose one of these databases to assign IP. In the model impact factor of publishing what time publication is published must be considered.

Consequently, the PA can be decomposed as follows:

$$PA = \sum PT * (CLR + IPT + DBPT + GDPT + GP + MP + IP)$$

### **Pseudo Cases**

To show how the model works, this study presents two pseudo cases. The first case is related to performance appraisal in institutions, while the second case demonstrates ranking individuals in a given discipline or field.

#### *Pseudo Case 1 for performance appraisal*

Table 5 presents the coding for and RBEI calculation of a researcher's performance appraisal.

The researcher's first publication was published in 1998. The current year is accepted as 2018.

Within this period the researcher produced 15 publications (Column A in Table 5). Column B shows publication years. Citation numbers in the current year (CN) were retrieved from the Web of Science database. The other columns (D, E, F, G, H, I, and J) were filled out based on the details shared in the previous section. Consequently, PA was calculated for each publication as follows:

$$PA = L = (D * (E + F + G + H + I + J + K))$$

-----  
 Insert Table 5 about here  
 -----

Table 6 demonstrates the calculation of RBEI for a researcher's performance appraisal by using data from Table 5. RBEI was calculated for the last five years in order to see the changes in the

1  
2  
3 researcher's RBEIs. Institutions may use the percentages of changes to identify faculty's  
4  
5 research performance.

15

### 16 *Pseudo Case 2 for ranking individuals*

17  
18 This model is useful for ranking individuals in a given discipline or field, in this case hospitality  
19  
20 and tourism. For example, a researcher would like to rank individuals who generated  
21  
22 publications related to "topic A." First, the researcher must decide publication type, and then  
23  
24 extract the publications. Second, the researcher should create a coding table (similar to Table 5)  
25  
26 for each author published in relation to topic A. Third, the researcher should generate an RBEI  
27  
28 score for each author from a coding table (similar to Table 6). Last, the researcher should rank  
29  
30 the authors based on the RBEI scores.  
31  
32

33  
34  
35 Table 7, Table 8, and Table 9 present the coding tables of three researchers (R1, R2, and R3)  
36  
37 who have published in relation to topic A. In this ranking, only research notes and full-text  
38  
39 articles published in the Social Science Citation Index's journals are considered. To create the  
40  
41 coding tables, the following codes in the current study were assigned.  
42  
43

44

## CONCLUSIONS

The present study proposed a new approach for ranking individuals in a given discipline or field and evaluating researchers' performances in an institution. This study used brand equity to establish its approach. To show how the model works, two pseudo cases were presented. This study has significant implications by introducing a new model to the field of research. These implications are discussed below.

The main contribution of this study is to introduce a new model for individuals' ranking and the performance appraisal of researchers in the fields of hospitality and tourism. Previous models have ranked researchers based on the quantity or quality of their publications, as defined by number of publications or number of times their work was cited, respectively (Dev et al. 2015; Law, 2017). The current model is more holistic since it is based on the idea of brand equity. In this model, brand equity encompasses three components: perceived quality as defined by publication attributes, perceived image as defined by number of coauthors, and perceived loyalty as defined by citation numbers per publication. Additionally, this model considers the longevity of a researcher's publication life. This model offers controllable performance indicators to researchers. For example, the previous models consider citation numbers, which researchers cannot control. In the current model, two out of three indicators (CoN and PA) are controllable. Therefore, researchers may increase their brand equity score or performance by focusing on these indicators in the publication generation process.

1  
2  
3 The hospitality and tourism academic community has two important issues that have not  
4 been resolved in many years. One of them is related to conducting interdisciplinary or  
5 multidisciplinary research in the field, since a strong attachment to the field is one of the main  
6 barriers to interdisciplinary research (Okumus et al., 2018). Another issue is the low  
7 representation of females in the academic research community (Munar et al., 2015). This model  
8 helps to minimize these problems in academia.  
9

### 10 11 12 *Practical implications*

13 The model is applicable for not only the fields of hospitality and tourism but also other  
14 disciplines. By adopting this model, a better performance appraisal system can be established.  
15 This model can be used by institutions and researchers who rank individuals in a given field.  
16 Additionally, some ranking databases such as Google Scholar Analytics, ResearchGate, Scopus  
17 and Mendeley may adapt their ranking system with this model to provide more holistic ranking  
18 models.  
19

### 20 21 22 **Limitations and Future Studies**

23 The proposed model has a few limitations. First, to measure brand image and brand  
24 loyalty, the model considers only one indicator for each component. This highlights  
25 opportunities for researchers to identify new indicators. Second, the effects of social media in the  
26 brand equity of researchers are ignored. Researchers may develop new indicators of brand  
27 image. Last, since our study's intent is not to rank or evaluate individual faculty members, we  
28 show how the model is useful, beneficial, and applicable rather than providing a ranking example  
29 of faculty in the fields of hospitality and tourism. These limitations provide new research  
30 questions and potential areas of study. First, this study can be repeated to rank individuals.
